In lecture, Jeff described an algorithm of Karatsuba that multiplies two $n$-digit integers using $O\left(n^{\lg 3}\right)$ single-digit additions, subtractions, and multiplications. In this lab we'll look at some extensions and applications of this algorithm.

1. Describe an algorithm to compute the product of an $n$-digit number and an $m$-digit number, where $m<n$, in $O\left(m^{\lg 3-1} n\right)$ time.
2. Describe an algorithm to compute the decimal representation of $2^{n}$ in $O\left(n^{\lg 3}\right)$ time.
[Hint: Repeated squaring. The standard algorithm that computes one decimal digit at a time requires $\Theta\left(n^{2}\right)$ time.]
3. Describe a divide-and-conquer algorithm to compute the decimal representation of an arbitrary $n$-bit binary number in $O\left(n^{\lg 3}\right)$ time.
[Hint: Let $x=a \cdot 2^{n / 2}+b$. Watch out for an extra log factor in the running time.]

## Think about later:

4. Suppose we can multiply two $n$-digit numbers in $O(M(n))$ time. Describe an algorithm to compute the decimal representation of an arbitrary $n$-bit binary number in $O(M(n) \log n)$ time.
